For each NNAP audit measure, there is an associated rate of missing entries. The rate of missing entries is described as M/T, where M is the number of missing entries and T is the number of all cases. To summarise data completeness across all NNAP measures, an average was taken of the rates of missing entries associated with a given unit. This methodology was applied to the 2018 data shown in this report (see Table A).

ROP was not included in the data completeness summary measure as it is not possible to differentiate between a negative (“never screened”) outcome and missing data. Infection data are known to be incompletely entered on to the BadgerNet system and are omitted from the data completeness summary measure. In addition, it is not possible to calculate a rate of missing entries for the number of care days given for the minimising avoidable mother baby separation measures, so these measures are also omitted.

For the NEC, BPD and Encephalopathy measures, the rate of missing entries is derived from the completeness of the daily or episodic data items used to categorise the results for these measures for the 2018 data year. This ensures units’ completeness is measured using the information they have responsibility for inputting into BadgerNet.

To calculate the number of eligible babies for one or more NNAP measures, a sum of all the eligible babies reported for each unit for the 2018 data year is taken.

Encephalopathy, mortality, and nurse staffing measures are not included in this count. Only eligible babies for the 2018 data year for the BPD measure are included in this count.

For full details of unit level missing data by measure, please see NNAP Online (www.nnap.rcpch.ac.uk/).
